Relativity, The Binomial Theorem, and Pythagorean Triples

From the decomposition of β into its space-time components $\beta = \frac{v}{c} = \left(\frac{x_v}{t_v} \frac{t_c}{x_c} \right)$, it is clear that the

“time dilation” equation $\tau' = \tau\gamma$ is a relation of linear metric density γ , where the metric “mass” is represented by $m = c\tau$ where $\tau = \frac{x}{c}$ and $x_v = x_c$ in the decomposition, so that $\tau' = \tau\gamma$.

The metric density γ (the variation in “mass” per unit length, where $m' = c\tau' = (c\tau)\gamma = m_0\gamma$) can be plotted against β and compared with the plot of integers for Pythagorean Triples,

where $\alpha^2 = \gamma^2 + \beta^2$ and $c^2 = a^2 + b^2$ For Special Relativity, where $\beta = \frac{v}{c}$, and c is taken to be an invariant, the relativistic unit circle restricts $\gamma=1$, $\beta=0$ to a single dimension; however, if c is allowed to vary, then the metric density $\gamma = \frac{1}{\sqrt{1 - (\frac{v}{c})^2}} = \frac{1}{\sqrt{1 - (\beta)^2}}$ changes with c as well, so the plot represents a change in mass density with respect to β with a change in c - i.e., an “acceleration” with respect to a constant v .

Note that in the plot $\beta \perp \gamma$, so that $\vec{\beta} \cdot \vec{\gamma} = 0$ and $\begin{vmatrix} \beta & 0 \\ 0 & \gamma \end{vmatrix} \rightarrow 2\gamma\beta(\vec{0})$ This is the condition that the “perturbation” is independent of γ , so that β is independent of the β_0 of the relativistic unit circle ($\gamma=1$) as a change in in the unit density from the formerly “final” condition where c is invariant. (This is also the case with the Lorentz Transform).

Thus the new β is associated with a second orthogonal dimension as a linear acceleration of the original metric.

If “Energy” is identified with area, the area of each triangle in the circle is equal to

$$E_{\gamma\beta}^a = \sqrt{\left(\frac{1}{2}\gamma\beta\right)^2} = \frac{1}{2}|\gamma\beta|, \text{ so the total energy due to the “interaction” represented by } |\gamma\beta| \text{ in each}$$

$$\text{quadrant is } E_{\gamma\beta} = 4\sqrt{\left(\frac{1}{2}\gamma\beta\right)^2} = 4\left(\frac{1}{2}|\gamma\beta|\right) = 2|\gamma\beta|$$

The total Energy of the system can then be represented by the individual energy due to the existence of each dimension plus the “interaction” energy $2|\gamma\beta|$:

$$E = \gamma^2 + \beta^2 + 2|\gamma\beta| \text{ However, in the case of the “linear” acceleration, there is no “interaction” between } \gamma \text{ and } \beta, \text{ since } \gamma \perp \beta, \text{ so } \vec{\beta} \cdot \vec{\gamma} = 0$$

The same is true of Pythagorean Triples for independent integers in the space (a, b) , since $\vec{a} \cdot \vec{b} = 0$, which results in the equation $c^2 = a^2 + b^2$

This can then be compared with the Binomial Theorem, where $c^2 = a^2 + b^2 + 2ab$ (and $\psi^2 = \gamma^2 + \beta^2 + 2\beta\gamma$) where the interaction energy is independent of the non-perturbed system so that $c^2 = a^2 + b^2$ (no multiplicative interaction between integers) and $\psi^2 = \gamma^2 + \beta^2$, respectively.

If the circle is distorted:

there will be interaction; in each case, however, the area of the triangle to the point (γ', β') or (a, b) relative to the γ or a axis will now be $A_{\gamma', \beta'} = \frac{1}{2} \gamma' \beta'$ or $A = \frac{1}{2} a' b'$, so the total energy will coincide with the Binomial Theorem for (γ', β') and (a', b') where $\bar{\gamma}'$ and $\bar{\beta}'$ (and \bar{a} and \bar{b}) are not

perpendicular, (i.e., (c', a', b') is not a Pythagorean Triple), so that $(c')^2 = (a')^2 + (b')^2 + 2(a'b')$ where $2a'b' = \text{rem}(a, b, n)$, a' and b' positive integers.

Thus a' and b' represent a “distortion” of the Pythagorean Circle from (a, b) .

The same is true for $\overline{\gamma'}$ and $\overline{\beta'}$, where $(\psi')^2 = \gamma'^2 + \beta'^2 + 2\gamma'\beta'$

In particular, note that c' cannot be an integer (since c included all possible integers in the cases of Pythagorean triples), and similarly for ψ' .

It is clear that $n = 2$ represents the number of dimensions in the analysis, and the “interaction” product represents an external interaction to the unperturbed systems (γ, β) and (a, b) . For the case $n = 2$, the perturbation can be eliminated by the expression $(\gamma' + i\beta')(\gamma' - i\beta') = (\gamma')^2 + (\beta')^2$ where the “imaginary” interaction $i\gamma\beta$ is “added” and “subtracted” simultaneously from the system (effectively “morphing” the distorted diagram back into a circle). Note that the area $2\gamma\beta$ is independent of rotation for a given angle θ in the case of an ellipse, corresponding to Kepler’s law.

For the case of higher dimensions $n > 2$ for the Binomial Theorem (positive definite energies, or bosons), it is impossible to eliminate interactions by the complex number relation, since the terms in $\text{rem}(a, b, n) > 0$ always in the relation $(c')^n = (a')^n + (b')^n + \text{rem}(a', b', n)$ where a', b' , and c' do not form a Pythagorean Triple.

For the Pythagorean Triple, $c = a + b$ means that $c^2 = a^2 + b^2$ where the left and right hand sides of the equality refer to the same unique integer without interaction between a and b , which for positive integers, can only be accomplished by adding and subtracting an imaginary interaction in the case of $c^2 = a^2 + b^2 = a^2 + b^2 + iab - iab$; otherwise, $c'^2 = (a' + b')^2 = a'^2 + b'^2 + 2a'b'$, which now includes the interactions. The latter equation can then be easily extended to the Binomial Expansion $(c')^n = (a')^n + (b')^n + \text{rem}(a', b', n)$, where c' cannot be an integer, since $\text{rem}(a', b', n) > 0$ for positive integers, thus proving Fermat’s Theorem.

In the case of General Relativity, the Binomial Theorem means that for a linear change in the value of c , the equation $(\psi')^n = (\gamma')^n + (\beta')^n + \text{rem}(\gamma, \beta, n)$ implies that ψ' cannot be an integer (even in the case of $n = 2$ for $(\psi')^2 = (\gamma')^2 + (\beta')^2 + 2\gamma'\beta'$ if there is an interaction between γ' and β'

If γ represents the energy due to electromagnetism and β' represents an interaction due to gravity, the equation becomes $(\psi')^2 = (\gamma')^2 + (\beta')^2 + 2\gamma\beta'$ where the components $2\gamma\beta'$ are the two-dimensional components of “gravitational” interaction. If β' represents a change in c , then this “gravitation” refers to “light-on-light” interaction – in QFT, a change in the value of Planck’s constant).

In any case, for a linear change in c , for powers of n , the interaction elements in $rem(\gamma, b', n)$ ensure that ψ' cannot be an integer, and correspond to the elements of the Jacobian of the metric tensor in the General Theory of Relativity, where γ represents electromagnetism at the “zero point” energy in the parking lot on earth at a given value of c (“temperature”), and β' refers to a change in temperature, whatever the interpretation (nightfall, gravity, observed non-circular orbit around the Sun, etc.).

In particular, the energy of the metric tensor cannot be an integer if there are interactions between its basis vectors for $n \geq 2$

There is much more to this story, but I don't have space to write it here... 😊
